Summary

Algorithms to optimally cover finite sets of matrices with diagonally-weight unit balls (with Euclidean operator norm) of matrices are considered. The motivation of this work is multi-model robust control design or covering of a finite set of plants with an additive or multiplicative uncertainty model.

- Reformulated as a semi-definite program.
- ‘Containment’ metric.
- Uncertainty model derived from frequency response data via frequency-by-frequency analysis.

Hindi, H., Seong, C-Y, and Boyd, S., “Computing optimal uncertainty models from frequency domain data,” Proceeding 41<sup>st</sup> IEEE Conf. Decision and Control, vol. 3, 2898–2905 (2002).

Summary

$\mathcal{R}$  denotes proper, rational functions, and  $\mathcal{R}^{n \times m}$  is the set of  $n \times m$  matrices with elements in  $\mathcal{R}$ . Similarly  $\mathcal{S}$  denotes stable (poles in open left-half plane), proper, rational functions. For any ring  $\mathcal{K}$ ,  $\mathcal{U}_{\mathcal{K}^{n \times n}}$  denotes the units in  $\mathcal{K}^{n \times n}$ . For  $G \in \mathcal{R}^{n \times m}$ , the notation  $U_{\#}(G)$  is the number of unstable eigenvalues in a stabilizable and detectable realization of  $G$ .

Given  $P \in \mathcal{R}^{n \times m}$ , and  $W_L \in \mathcal{U}_{\mathcal{S}^{n \times n}}$ ,  $W_R \in \mathcal{U}_{\mathcal{S}^{m \times m}}$

$$\mathcal{A}(P, W_L, W_R) := \left\{ \tilde{P} = P + W_L \Delta W_R : \Delta \in \mathcal{R}^{n \times m}, \|\Delta\|_{\mathcal{L}_{\infty}} \leq 1, U_{\#}(P) = U_{\#}(\tilde{P}) \right\}$$

$$\mathcal{M}_{\mathcal{I}}(P, W_L, W_R) := \left\{ \tilde{P} = P(I_m + W_L \Delta W_R) : \Delta \in \mathcal{R}^{n \times m}, \|\Delta\|_{\mathcal{L}_{\infty}} \leq 1, U_{\#}(P) = U_{\#}(\tilde{P}) \right\}$$

$$\mathcal{M}_{\mathcal{O}}(P, W_L, W_R) := \left\{ \tilde{P} = (I_n + W_L \Delta W_R)P : \Delta \in \mathcal{R}^{n \times m}, \|\Delta\|_{\mathcal{L}_{\infty}} \leq 1, U_{\#}(P) = U_{\#}(\tilde{P}) \right\}$$

Summary

**Theorem 0.1** (Additive) Given  $P \in \mathcal{R}^{n \times m}$ , and  $W_L \in \mathcal{U}_{\mathcal{S}^{n \times n}}$ ,  $W_R \in \mathcal{U}_{\mathcal{S}^{m \times m}}$ . Assume  $P$  has no poles on the imaginary axis. Then  $\tilde{P} \in \mathcal{R}^{n \times m}$  satisfies  $\tilde{P} \in \mathcal{A}(P, W_L, W_R)$  if and only if  $U_{\#}(P) = U_{\#}(\tilde{P})$  and

$$\begin{bmatrix} W_L W_L^* & \tilde{P} - P \\ (\tilde{P} - P)^* & W_R^* W_R \end{bmatrix} \succeq 0 \quad (1)$$

for all  $\omega \in \mathbf{R}$ .

**Theorem 0.2** (Input-multiplicative) Given  $P \in \mathcal{R}^{n \times m}$ , and  $W_L \in \mathcal{U}_{\mathcal{S}^{n \times n}}$ ,  $W_R \in \mathcal{U}_{\mathcal{S}^{m \times m}}$ . Assume  $P$  has no poles on the imaginary axis. Then  $\tilde{P} \in \mathcal{R}^{n \times m}$  satisfies  $\tilde{P} \in \mathcal{M}_{\mathcal{I}}(P, W_L, W_R)$  if and only if  $U_{\#}(P) = U_{\#}(\tilde{P})$  and

$$\begin{bmatrix} P W_L W_L^* P^* & \tilde{P} - P \\ (\tilde{P} - P)^* & W_R^* W_R \end{bmatrix} \succeq 0 \quad (2)$$

for all  $\omega \in \mathbf{R}$ .

Other over-bound uncertain models can also be represented via LMIs.

Containment Metric

Summary

Given a nominal model  $P \in \mathcal{R}^{n \times m}$ , and a finite collection of models  $\{P_i\}_{i=1}^N$  (assuming same # of RHP poles), find weights  $W_L$  and  $W_R$  be chosen so that for all  $i$

$$P_i \in \mathcal{A}(P, W_L, W_R) \quad \text{or} \quad P_i \in \mathcal{M}_I(P, W_L, W_R) \quad \text{or} \quad P_i \in \mathcal{M}_O(P, W_L, W_R)$$

Select  $W_L$  and  $W_R$  as “small” as possible, (approximately “radius” of the uncertain set).

Define new optimization variables  $L$  and  $R$  for  $W_L W_L^*$  and  $W_R^* W_R$  respectively.

- Summary

Optimization to determine small, feasible weights is:

1. Chose positive definite matrices  $\Gamma_1$  and  $\Gamma_2$
2. Pick a nominal plant model,  $P$
3. Grid the frequency axis using  $\{\omega_k\}_{k=1}^M$ .
4. At each frequency, solve the SDP

$$\min_{L \succ 0, R \succ 0} \text{Tr}\Gamma_1 L + \text{Tr}\Gamma_2 R$$

subject to

$$\begin{bmatrix} L & P_i - P \\ (P_i - P)^* & R \end{bmatrix} \succeq 0 \quad \text{or} \quad \begin{bmatrix} PLP^* & P_i - P \\ (P_i - P)^* & R \end{bmatrix} \succeq 0$$

for all  $\{i\}_{i=1}^N$ , and at all frequencies  $\{\omega_k\}_{k=1}^M$ .

# Cover Measures

- Introduction

- GTM Aircraft
- Data Set I
- Data Sets IP and IPN
- Data Set IP
- Data Set IPN
- Containment Metric
- Summary

Given  $C \in \mathbf{C}^{n \times m}$ ,  $D \in \mathbf{C}^{n \times n}$ ,  $E \in \mathbf{C}^{n \times m}$ , define

$$\mathcal{B}_\alpha(C, D, E) := \{C + D\Delta E : \Delta \in \mathbf{C}^{n \times n}, \bar{\sigma}(\Delta) \leq \alpha\}$$

When  $\alpha = 1$ ,  $\mathcal{B}(C, D, E)$ .

Given  $(C_1, D_1, E_1)$  and  $(C_2, D_2, E_2)$ , what is the smallest value of  $\alpha$  such  $\mathcal{B}_\alpha(C_1, D_1, E_1)$  contains  $\mathcal{B}(C_2, D_2, E_2)$ ? Suppose  $\mathcal{B}(C_1, D_1, E_1)$  and  $\mathcal{B}(C_2, D_2, E_2)$  are two different “covers” of a finite collection of matrices.

- How much does  $(C_1, D_1, E_1)$  have to be expanded to include all of  $\mathcal{B}(C_2, D_2, E_2)$ ?
- Conversely, how much does  $(C_2, D_2, E_2)$  have to be expanded to include all of  $\mathcal{B}(C_1, D_1, E_1)$ ?

Description which has to be expanded more is a less conservative cover. These are considered as *containment metrics*.

- Summary

**Theorem 0.3** *Theorem: Suppose  $n \geq m$ ,  $C_i \in \mathbf{C}^{n \times m}$ ,  $D_i \in \mathbf{C}^{n \times n}$ ,  $E_i \in \mathbf{C}^{n \times m}$ , with each  $D_i$  invertible, and each  $E_i$  full column rank. Then*

$$\min \{ \alpha : \mathcal{B}(C_2, D_2, E_2) \subset \mathcal{B}_\alpha(C_1, D_1, E_1) \} = \max_{\Delta_2 \in \mathbf{C}^{n \times n}, \bar{\sigma}(\Delta_2) \leq 1} \bar{\sigma} [M(\Delta_2)]$$

where  $M(\Delta) = D_1^{-1} (C_2 - C_1 + D_2 \Delta E_2) (E_1^* E_1)^{-\frac{1}{2}}$  Moreover, the maximization can be computed reliably and accurately with structured singular value/SDP methods.

Special cases:

- Input-multiplicative model must be increased by a factor  $\bar{\sigma} [(PW_1)^{-1} W_3] \bar{\sigma} [W_4 W_2^{-1}]$  to contain the additive model
- Additive model must be increased by a factor  $\bar{\sigma} [W_3^{-1} (PW_1)] \bar{\sigma} [W_2 W_4^{-1}]$  to contain the input-multiplicative model.

- Containment Metric**
- Summary

Compare conservatism of these relative model sets for IP:

- $P_{\text{in}} = P_{\text{nom}}(I + W_1\Delta_{\text{in}}W_2)$
- $P_{\text{add}} = P_{\text{nom}} + W_3\Delta_{\text{add}}W_4$

Containment metric for additive uncertainty over-bound weights relative to the input multiplicative over-bound model,  $P_{\text{add}}(W_3, W_4) \in P_{\text{in}}(W_1, W_2)$  is at each frequency  $\omega$ .

$$|\Delta_{\text{add}}| = \bar{\sigma}(W_3^{-1}P_{\text{nom}}W_1)\bar{\sigma}(W_2W_4^{-1}), \quad \text{at } \omega$$

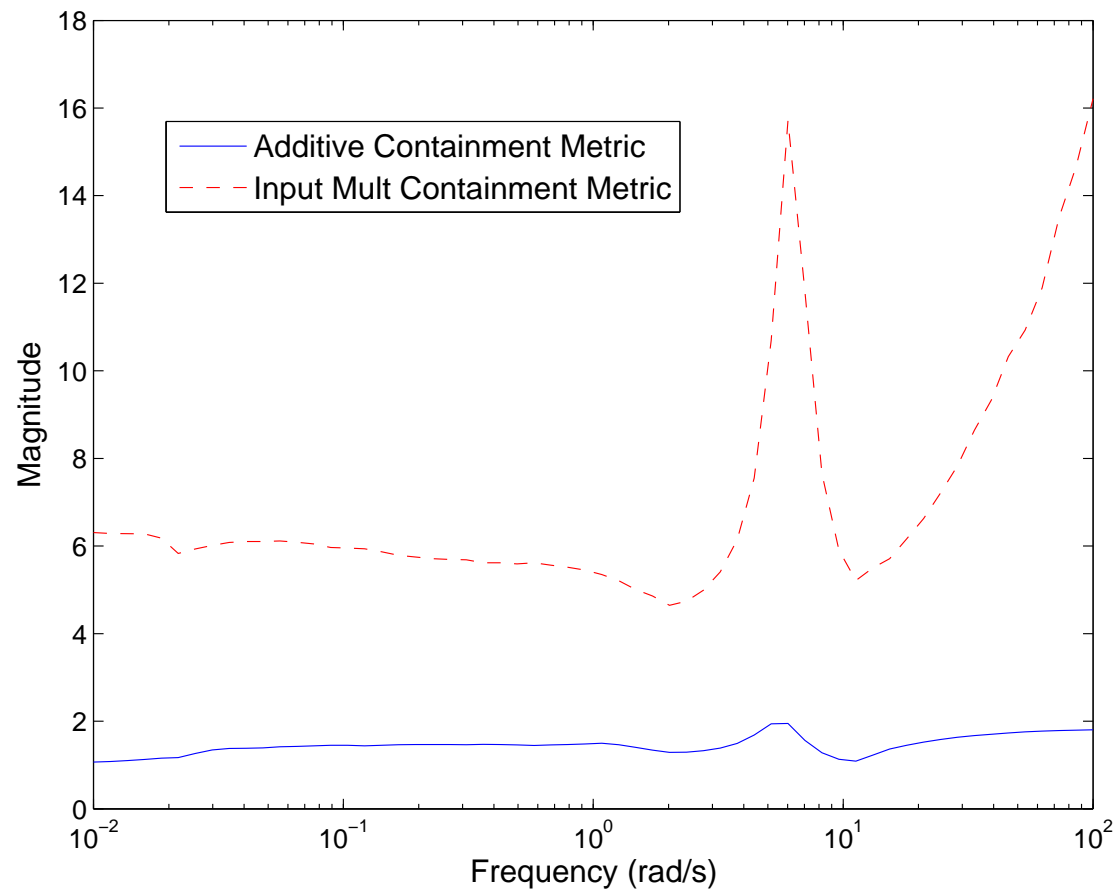

Input multiplicative over-bound weights relative to additive uncertainty over-bound weights

$$|\Delta_{\text{in}}| = \bar{\sigma}((P_{\text{nom}}W_1)^{-1}W_3)\bar{\sigma}(W_4W_2^{-1}), \quad \text{at } \omega$$
