

Modeling & Control of Hybrid Systems

Chapter 5 – Switched Control

Overview

1. Introduction & motivation for hybrid control
2. Stabilization of switched linear systems
3. Time-controlled switching & pulse width modulation
4. Sliding mode control
5. Stabilization by switching control

hs_switched_ctrl.1

1.1 Motivation for switched controllers

Theorem (Brockett's necessary condition)

Consider system

$$\dot{x} = f(x, u) \quad \text{with } x \in \mathbb{R}^n, u \in \mathbb{R}^m, f(0, 0) = 0$$

where f is smooth function.

If system is asymptotically stabilizable (around $x = 0$) using *continuous* feedback law $u = \alpha(x)$, then image of every open neighborhood of $(x, u) = (0, 0)$ under f contains open neighborhood of $x = 0$

hs_switched_ctrl.3

1. Introduction & motivation for hybrid control

Several “classical” control methods for continuous-time systems are hybrid:

- variable structure control
- sliding mode control
- relay control
- gain scheduling
- bang-bang time-optimal control
- fuzzy control

→ common characteristic: **switching**

hs_switched_ctrl.2

1.1 Motivation for switched controllers (continued)

- For non-holonomic integrator: $\dot{x} = u$

$$\dot{y} = v$$

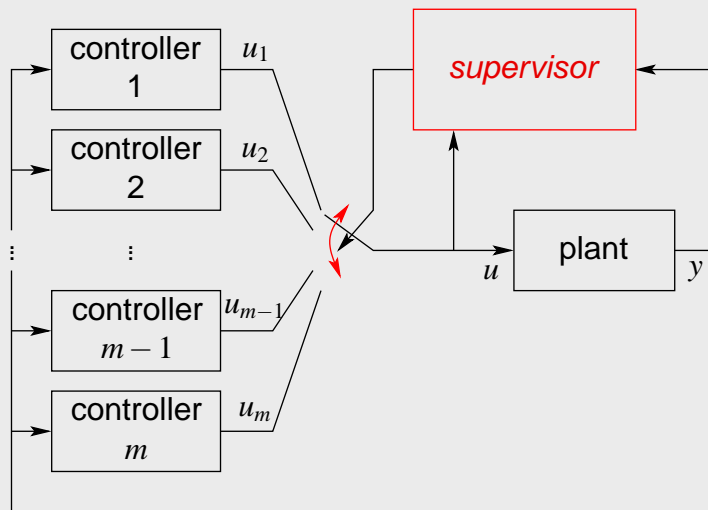

$$\dot{z} = xv - yu$$

- Is asymptotically stabilizable (see later)
- Satisfies Brockett's necessary condition?
 - if $f_1 = f_2 = 0$ then $f_3 = 0$
 - hence, $(0, 0, \varepsilon)$ cannot belong to image of f for any $\varepsilon \neq 0$
 - image of open neighborhood of $(x, u) = (0, 0)$ under f does *not* contain open neighborhood of $(x, y, z) = (0, 0, 0)$
 - so non-holonomic integrator cannot be stabilized by continuous feedback

→ hybrid control schemes necessary to stabilize it!

hs_switched_ctrl.4

1.2 Switching control/logic

hs_switched_ctrl.5

1.2 Switching control/logic (continued)

Main problem: **Chattering** (i.e., very fast switching)

1. Hysteresis switching logic

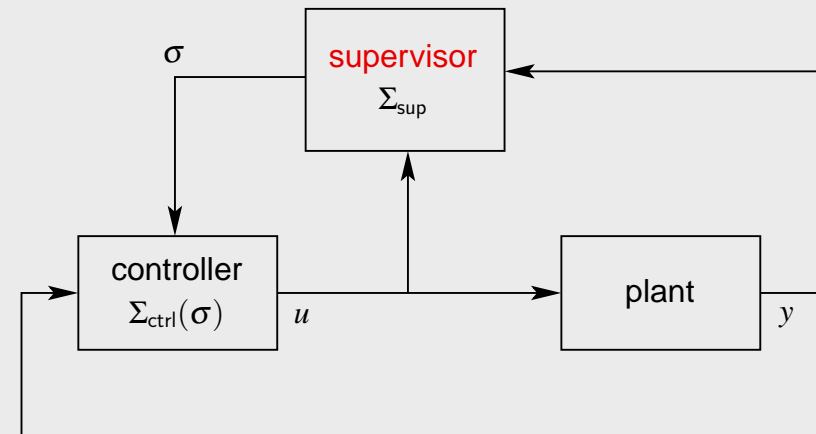

- Let $h > 0$, let π_σ be a performance criterion (to be minimized)
- If supervisor changes value of σ to q , then σ is held *fixed* at q until $\pi_p + h < \pi_q$ for some p
 - σ is set equal to p
 - ⇒ threshold parameter $h > 0$ prevents infinitely fast switching
- Similar idea: **boundary layer** around switching surface in sliding mode control

2. Dwell-time switching logic

once symbol σ is chosen by supervisor it remains constant for at least $\tau > 0$ time units (τ : “dwell time”)

hs_switched_ctrl.7

1.2 Switching control/logic (continued)

→ shared controller state variables

hs_switched_ctrl.6

2. Stabilization of switched linear systems via suitable switching (Problem C)

$$\dot{x} = A_i x, \quad i \in I := \{1, 2, \dots, N\}$$

Find switching rule σ as function of time/state such that closed-loop system is asymptotically stable

2.1 Quadratic stabilization via *single* Lyapunov function

Select $\sigma(x) : \mathbb{R}^n \rightarrow I := \{1, 2, \dots, N\}$ such that closed-loop system has single quadratic Lyapunov function $x^T P x$

One solution: if some convex combination of A_i is stable:

$$A := \sum \alpha_i A_i \quad (\alpha_i \geq 0, \sum \alpha_i = 1) \text{ is stable}$$

Select $Q > 0$ and let $P > 0$ be solution of $A^T P + P A = -Q$

hs_switched_ctrl.8

Quadratic stabilization (continued)

- From $x^T(A^T P + PA)x = -x^T Qx < 0$ it follows that

$$\sum_i \alpha_i [x^T(A_i^T P + PA_i)x] < 0$$

- For each x there is at least one mode with $x^T(A_i^T P + PA_i)x < 0$ or stronger

$$\bigcup_{i \in I} \{x \mid x^T(A_i^T P + PA_i)x \leq -\frac{1}{N}x^T Qx\} = \mathbb{R}^n$$

- Switching rule:

$$i(x) := \arg \min x^T(A_i^T P + PA_i)x$$

- Leads possibly to sliding modes. Alternative?

hs_switched_ctrl.9

2.2 Stabilization via multiple Lyapunov functions (Problem C)

Main idea: Find function $V_i(x) = x^T P_i x$ that decreases for $\dot{x} = A_i x$ in some region

Define $\mathcal{X}_i := \{x \mid x^T[A_i^T P_i + P_i A_i]x < 0\}$

If $\mathcal{X}_1 \cup \mathcal{X}_2 = \mathbb{R}^n$, try to switch to satisfy multiple Lyapunov criterion to guarantee asymptotic stability.

Find P_1 and P_2 such that they satisfy the coupled conditions:

$$x^T(P_1 A_1 + A_1^T P_1)x < 0 \text{ when } x^T(P_1 - P_2)x \geq 0, x \neq 0$$

and

$$x^T(P_2 A_2 + A_2^T P_2)x < 0 \text{ when } x^T(P_2 - P_1)x \geq 0, x \neq 0$$

Then $\sigma(t) = \arg \max\{V_i(x(t)) \mid i = 1, 2\}$ is stabilizing (V_σ will be continuous)

hs_switched_ctrl.11

Alternative switching rule for quadratic stabilization

- Modified switching rule (based on hysteresis switching logic):

– stay in mode i as long as $x^T(A_i^T P + PA_i)x \leq -\frac{1}{2N}x^T Qx$

– when bound reached, switch to a new mode j that satisfies

$$x^T(A_j^T P + PA_j)x \leq -\frac{1}{N}x^T Qx$$

- There is a lower bound on the duration in each mode!
- No conservatism for 2 modes (necessary & sufficient for this case):

Theorem: If there exists a quadratically stabilizing state-dependent switching law for the switched linear system with $N = 2$, then matrices A_1 and A_2 have a stable convex combination

hs_switched_ctrl.10

2.3 S-procedure

S-procedure If there exist $\beta_1, \beta_2 \geq 0$ such that

$$-P_1 A_1 - A_1^T P_1 + \beta_1 (P_2 - P_1) > 0$$

$$-P_2 A_2 - A_2^T P_2 + \beta_2 (P_1 - P_2) > 0$$

then $\sigma(t) = \arg \max\{V_i(x(t)) \mid i = 1, 2\}$

→ only finds switching sequence (discrete inputs)!

What if also continuous inputs are present?

hs_switched_ctrl.12

2.4 Stabilization of switched linear systems with continuous inputs

Switched linear system with inputs:

$$\dot{x} = A_i x + B_i u, \quad i \in I = \{1, \dots, N\}$$

Now both $\sigma : [0, \infty) \rightarrow I$ and feedback controllers $u = K_i x$ are to be determined

Case 1: Determine K_i such that closed loop stable under arbitrary switching (assuming we **know** mode)!

Case 2: Determine both $\sigma : [0, \infty) \rightarrow I$ and K_i

Case 3 (for PWL systems): Given σ as function of state, determine K_i

hs_switched_ctrl.13

3. Time-controlled switching & pulse width modulation

If dynamical system switches between several subsystems
→ stability properties of total system may be quite different from those of subsystems

hs_switched_ctrl.15

Case 1: Stabilization of switched linear system under arbitrary switching

$$\dot{x} = A_i x + B_i u, \quad i \in I = \{1, \dots, N\}$$

Sufficient condition: find common *quadratic* Lyapunov function $V(x) = x^T P x$ for some positive definite matrix P and K_1, \dots, K_N

$$(A_i + B_i K_i)^T P + P(A_i + B_i K_i) < 0 \text{ for all } i = 1, \dots, N \text{ and } P > 0$$

→ LMIs (also for Cases 2 and 3)

→ state-based switching in this section, ... next ...

hs_switched_ctrl.14

3.1 Time-controlled switching

- $x(t_0 + \frac{1}{2}\epsilon) = \exp(\frac{1}{2}\epsilon A_1)x_0 = x_0 + \frac{\epsilon}{2}A_1 x_0 + \frac{\epsilon^2}{8}A_1^2 x_0 + \dots$
 $x(t_0 + \epsilon) = (I + \frac{\epsilon}{2}A_2 + \frac{\epsilon^2}{8}A_2^2 + \dots)(I + \frac{\epsilon}{2}A_1 + \frac{\epsilon^2}{8}A_1^2 + \dots)x_0$
 $= (I + \epsilon[\frac{1}{2}A_1 + \frac{1}{2}A_2] + \frac{\epsilon^2}{8}[A_1^2 + A_2^2 + 2A_2A_1] + \dots)x_0.$
- Compare with
 $\exp[\epsilon(\frac{1}{2}A_1 + \frac{1}{2}A_2)] = I + \epsilon[\frac{1}{2}A_1 + \frac{1}{2}A_2] + \frac{\epsilon^2}{8}[A_1^2 + A_2^2 + A_1A_2 + A_2A_1] + \dots$
→ same for $\epsilon \approx 0$
- So for $\epsilon \rightarrow 0$ solution of switched system tends to solution of
 $\dot{x} = (\frac{1}{2}A_1 + \frac{1}{2}A_2)x$ (“averaged” system)
- Possible that A_1 and A_2 are stable, whereas matrix $\frac{1}{2}A_1 + \frac{1}{2}A_2$ is unstable, or vice versa

hs_switched_ctrl.16

Example

- Consider

$$A_1 = \begin{bmatrix} -0.5 & 1 \\ 100 & -1 \end{bmatrix}, \quad A_2 = \begin{bmatrix} -1 & -100 \\ -0.5 & -1 \end{bmatrix}$$

- A_1, A_2 unstable, but matrix $\frac{1}{2}(A_1 + A_2)$ is stable
→ switched system should be stable if frequency of switching is sufficiently high
- Minimal switching frequency found by computing eigenvalues of the mapping $\exp(\frac{1}{2}\epsilon A_1) \exp(\frac{1}{2}\epsilon A_2)$ (Why?)

hs_switched_ctrl.17

Example (continued)

for $\epsilon = 0.02$

hs_switched_ctrl.19

Example (continued)

→ maximal value of ϵ : 0.04 (=50 Hz)

hs_switched_ctrl.18

3.2 Pulse width modulation

- Assume mode 1 followed during $h\epsilon$, and mode 2 during $(1-h)\epsilon$
→ behavior of system is well approximated by system

$$\dot{x} = (hA_1 + (1-h)A_2)x$$

- Parameter h might be considered as control input
- If h varies, should be on time scale that is much slower than the time scale of switching
- If mode 1 is “power on” and mode 2 is “power off”, then h is known as *duty ratio*
- Power electronics: fast switching theoretically provides possibility to regulate power without loss of energy
→ used in power converters (e.g., Boost converter)

hs_switched_ctrl.20

3.2 Pulse width modulation (continued)

- System: $\dot{x} = f(x, u)$, $u \in \{0, 1\}$
- Duty cycle: Δ (fixed)
- u is switched exactly one time from 1 to 0 in each cycle
- Duty ration α : fraction of duty cycle for which $u = 1$

$$u(\tau) = 1 \quad \text{for } t \leq \tau < t + \alpha\Delta$$

$$u(\tau) = 0 \quad \text{for } t + \alpha\Delta \leq \tau < t + \Delta$$

- Hence, $x(t + \Delta) = x(t) + \int_t^{t+\alpha\Delta} f(x(\tau), 1) d\tau + \int_{t+\alpha\Delta}^{t+\Delta} f(x(\tau), 0) d\tau$

- Ideal averaged model ($\Delta \rightarrow 0$):

$$\dot{x}(t) = \lim_{\Delta \rightarrow 0} \frac{x(t + \Delta) - x(t)}{\Delta} = \alpha f(x(t), 1) + (1 - \alpha) f(x(t), 0)$$

hs_switched_ctrl.21

4. Sliding mode control (continued)

- Assume “desired behavior” whenever constraint $s(x) = 0$ is satisfied
- Set $\{x \mid s(x) = 0\}$ is called *sliding surface*
- Find control law u such that

$$\frac{1}{2} \frac{d}{dt} s^2 \leq -\alpha |s|$$

where $\alpha > 0$

→ squared “distance” to sliding surface decreases along all system trajectories

hs_switched_ctrl.23

4. Sliding mode control

- Consider $\dot{x}(t) = f(x(t), u(t))$ with u scalar
- Suppose switching feedback control scheme:

$$u(t) = \begin{cases} \phi_+(x(t)) & \text{if } h(x(t)) > 0 \\ \phi_-(x(t)) & \text{if } h(x(t)) < 0 \end{cases}$$

- Surface $\{x \mid h(x) = 0\}$ is called *switching surface*
- Let $f_+(x) = f(x, \phi_+(x))$ and $f_-(x) = f(x, \phi_-(x))$, then

$$\dot{x} = \frac{1}{2}(1 + v)f_+(x) + \frac{1}{2}(1 - v)f_-(x), \quad v = \text{sgn}(h(x))$$

- Use solutions in Filippov’s sense if “chattering”

hs_switched_ctrl.22

Properties of sliding mode control

- Quick succession of switches may occur
 - increased wear, high-frequency vibrations
 - ⇒ - embed sliding surface in thin *boundary layer*
 - smoothen discontinuity by replacing sgn by steep sigmoid function
 - Note: modifications may deteriorate performance of closed-loop system
- Main advantages of sliding mode control:
 - conceptually simple
 - robustness w.r.t. uncertainty in system data
- Possible disadvantage:
 - excitation of unmodeled high-frequency modes

hs_switched_ctrl.24

5. Stabilization by switching control

- For multi-model *linear* systems
→ use techniques for quadratic stabilization using single or multiple Lyapunov function
- Stabilization of non-holonomic systems using hybrid feedback control (e.g., non-holonomic integrator)
→ rather ad hoc
not structured
complicated analysis and proofs

hs_switched_ctrl.25

Stabilization of non-holonomic integrator (continued)

- Since $V(t) = V(0)e^{-2t} = \frac{1}{2}(x^2(0) + y^2(0))e^{-2t}$
condition for system to be asymptotically stable is
$$\frac{1}{2}(x^2(0) + y^2(0)) \geq |z(0)|$$

→ defines parabolic region $\mathcal{P} = \{(x, y, z) \mid 0.5(x^2 + y^2) \leq |z|\}$
 - If initial conditions do *not* belong to \mathcal{P} then sliding mode control asymptotically stabilizes system
 - If initial state is inside \mathcal{P} :
 - first use control law (e.g., nonzero constant control) to steer system outside \mathcal{P}
 - then use sliding mode control
- **hybrid control scheme**

hs_switched_ctrl.27

Stabilization of non-holonomic integrator

- System: $\dot{x} = u, \quad \dot{y} = v, \quad \dot{z} = xv - yu$
- Sliding mode control: $u = -x + y \operatorname{sgn}(z)$
 $v = -y - x \operatorname{sgn}(z)$
- Lyapunov function for (x, y) subspace: $V(x, y) = \frac{1}{2}(x^2 + y^2)$
 $\Rightarrow \dot{V} = -x^2 + xy \operatorname{sgn}(z) - y^2 - xy \operatorname{sgn}(z) = -(x^2 + y^2) = -2V$
 $\Rightarrow x, y \rightarrow 0$
- $\dot{z} = xv - yu = -(x^2 + y^2) \operatorname{sgn}(z) = -2V \operatorname{sgn}(z)$
So $|z|$ will decrease and reach 0 provided that
$$2 \int_0^\infty V(\tau) d\tau > |z(0)|$$

→ z will reach 0 in finite time

hs_switched_ctrl.26
